

Google
Pixel 10 Pro XL

For this video we used Google Nano Banana Pro for image generation and Google Veo3 First/Last Frame for video generation. With this method you can do impossible camera movements and transitions between all your different videos with no visible cuts.

First Frame

Last Frame

Prompt:

Start on a close-up hero angle of the Google Pixel 10 Pro XL, filling the frame as the camera glides along the back toward the camera bar, highlighting the lenses and material precision. Subtle reflections move naturally across the polished metal edges and matte glass. The camera then smoothly pulls back, opening into a wide, elegant product shot with the phone floating against a soft golden haze. Lit from above, warm reflections accent the metallic frame while the background haze shifts gently in depth, maintaining a consistent, premium spotlight feel. The shot settles in a refined wide hero view.

First Frame

Last Frame

Prompt:

Start on a wide rear shot of the Google Pixel 10 Pro XL, with the camera bar near the top as soft haze drifts behind. The camera begins a slow push-in, gliding downward along the back of the phone as the device gently rotates, tilting the bottom edge forward toward the camera. The camera lowers and moves beneath the phone, staying centered as it dips under and reorients. The movement resolves with the lens perfectly level with the bottom edge, ending on a clean, symmetrical, front-facing view of the charging port, with natural metal reflections and subtle haze motion completing the single continuous move.

First Frame

Last Frame

Prompt:

Start on a stable bottom view of the phone, centered on the charging port. The camera begins a gentle FPV-style glide toward the opening, with subtle micro-movements and no harsh motion. As the phone rotates slightly, the camera aligns and slips inside. The interior reveals a dense network of blue circuitry as the camera follows a smooth forward path, banking through tight corridors. Passing close to components, blue light streaks activate connectors and nearby clusters, creating a sequential startup effect. The camera flows through multiple interior levels, fast but stable, guided by illuminated pathways reacting to its movement.

First Frame

Last Frame

Prompt:

The movement begins with a forward rush through dense green-lit circuitry. Midway, the camera follows a wide curved path that smoothly redirects toward the backside of the phone rather than the top edge, maintaining an aerodynamic FPV feel. As it approaches the rear, a vertical shaft of gold and glass appears, revealing the camera housing interior. The camera tilts upward and rises through the lens chamber as optical layers streak past and internal light fades into exterior haze. Breaking through the outer lens glass, the camera completes a clean, continuous zoom-out, resolving in a frontal close-up of the camera module with no cuts.

First Frame

Last Frame

Prompt:

Use the same sideways close up of the Pixel camera module as the fixed starting angle, keeping this orientation. The camera performs a tight semicircular orbit around the camera glass, staying close as it slides smoothly around the surface. During the orbit, visible components separate in depth along the glass axis: the black glass cover lifts first, followed by the two circular lenses, the periscope rectangle sliding on its true axis, then the flash and small sensor, with the gold frame detaching last. Only separate elements visible in the starting image. Preserve premium lighting and materials for a clean, physically grounded exploded view.

First Frame

Last Frame

Prompt:

Begin on the exploded camera module exactly as shown, with all lens elements, prism, sensor blocks, periscope unit, flash, and gold top plate visible and unchanged. Animate only one action: each piece moves directly inward toward its original position, never drifting outward, leaving frame, or changing scale. One by one, elements slide back into their precise slots until the module is fully reassembled. The camera holds the same angle throughout. Once sealed, the phone rotates smoothly in midair as a realistic hand reaches in and catches it naturally. Maintain the same soft warm background with subtle atmospheric movement.

First Frame

Last Frame

Prompt:

Start with the close shot of him holding the phone in his right hand with the back facing the camera. He moves his left hand in, holds the phone with both hands, and turns it so the screen faces him in one smooth motion.

First Frame

Last Frame

Prompt:

Begin with the same frontal shot of the man using his phone, matching pose, lighting, clothing, and background exactly. He continues looking at the screen and interacting naturally. The camera slowly orbits to the right in one smooth, continuous move, gentle and minimal, transitioning from frontal to an over-the-shoulder angle. As the camera reaches the back side, the phone screen is clearly visible facing him, matching the reference view. Keep the background soft and seamless with the same warm spotlight mood and no visible light sources. Maintain accurate proportions and continuity of his hands, phone, and posture throughout.
